

# Chapter 1

## Introduction to Thermo/Stat. Mech 1.1

First let's look at some quotes about Thermo

- Arnold Sommerfeld: Thermo is hard!
- Albert Einstein: Classical thermo is important.

What about Statistical Mech? → it's the bridge (see Figure)

In this class we'll focus on the macroscopic until November → chp 17 deals w/ Stat. Mech

Speaking of the syllabus, let's all look at it now...

...ok, so let's talk more about "What is Thermo?"

→ it started in ~1770 with people trying to figure out how things heat up and cool down (caloric theory)

→ the equivalence of heat and work was found in 1798 by Count Rumford while drilling canons.

Now we'll do a demo...

1.2

- That demo was the same thing that James Joule (who was inspired by Rumford) did in ~1840.

- The second demo shows the conversion of heat back into work.

↳ Sadi Carnot realized<sup>in 1820</sup> that there is an upper limit to how much heat can be converted to work

↳ We'll see in chapter 3 that this upper limit depends on the absolute temperatures of the hot body and of the cold body (heat is "transfer of energy from hot body to cold body")

- So, two experiments (work  $\rightarrow$  heat, and heat  $\rightarrow$  work) started people thinking in a whole new way.

- In the end, they found out that it is more convenient to discuss energy by specifying additional parameters

↳ Internal Energy,  $U$ , is the energy of a system w/  $S + V$  fixed

↳ Enthalpy,  $H$ , " " " " " " " w/  $S + P$  fixed

↳ Gibbs Free Energy,  $G$ , " " " " " " " w/  $P + T$  fixed

↳ Helmholtz Free Energy,  $F$ , " " " " " " " w/  $T + V$  fixed

- These 4 kinds of energies can be understood by an analogy to money: stocks, bonds, mutual funds, T-bills all are \$

1.3

Now, let's look again at our PowerPoint slides handout:

- system vs. surroundings
- open vs. closed vs. isolated vs. adiabatic

We'll look at these again next lecture
